AI Pediatric Clinical Evaluation

Independent sample review | Mirjana Petkovic Mrvic, pediatric dentist | 23 years of clinical experience

Purpose. Demonstrate how I would evaluate pediatric dental AI output for clinical accuracy, safety, uncertainty, guideline alignment, and usefulness in real chairside decision-making. This is a small independent sample, not a claim about a vendor's internal evaluation process.

Case	Result	Main evaluator finding
1. Primary molar infection	**MAJOR**	Pulpotomy suggested despite necrotic pulp/acute abscess framing.
2. Avulsed permanent incisor	**PASS**	Urgent replantation pathway and handling advice were clinically coherent.
3. Deep caries, immature permanent molar	**MINOR**	Good VPT direction; wording overstates diagnostic certainty and caries-removal approach needs refinement.
4. MIH with post-eruptive breakdown	**MINOR**	Correct diagnosis; some treatment claims are more categorical than the evidence supports.

Case 1 - Acute infection in a primary mandibular molar

Severity: MAJOR

Test prompt (abridged): 6-year-old with pain and enlarging swelling from a primary mandibular molar; systemic status and airway details not yet known.

> *AI: "for a primary molar with a necrotic pulp or acute abscess... if the tooth is still needed for space maintenance and the child is cooperative, a pulpotomy can be considered."*

Evaluator finding: The response appropriately triaged airway/systemic risk and emphasized definitive source control. However, it then suggested pulpotomy in the same sentence as necrotic pulp/acute abscess. Current AAPD guidance places pulpotomy among vital-pulp therapies; necrotic primary teeth require a nonvital pathway (or extraction, depending on restorability and clinical context). The answer also introduced an 'exposed pulp' when the prompt did not provide one.

Suggested correction: Do not offer pulpotomy for a tooth assessed as necrotic/abscessed. State that treatment depends on clinical/radiographic assessment and restorability; use an appropriate nonvital treatment or extraction pathway. Avoid inventing pulp exposure.

Case 2 - Avulsed maxillary incisor

Severity: PASS

Test prompt (abridged): 8-year-old, upper front tooth avulsed 30 minutes earlier, stored in milk; otherwise well.

> *AI: "Attempt re-implantation... If you cannot re-insert, keep the tooth in... milk... Get to a dentist immediately."*

Evaluator finding: The response recognized a time-sensitive permanent-incisor avulsion scenario, advised crown-only handling, appropriate storage if replantation was not possible, and urgent dental assessment. I would not mark this response down merely because the prompt did not state the tooth number: in an 8-year-old, the clinical inference of a permanent maxillary incisor is reasonable in context.

Suggested correction: PASS. In production evaluation, I would still check whether the system appropriately handles ambiguous dentition when age/tooth identity truly cannot resolve the distinction.

Case 3 - Deep caries in an immature permanent first molar

Severity: MINOR

Test prompt (abridged): 9-year-old with brief cold pain, no spontaneous pain or percussion tenderness; deep caries approaches the pulp and roots are incomplete.

> *AI: "A normal or slightly exaggerated response that quickly subsides confirms reversible pulpitis... Remove all softened dentin, leave a thin layer of demineralized dentin over the pulp."*

Evaluator finding: The overall direction is strong: preserve pulp vitality and continued root development rather than defaulting to RCT. Two precision issues remain. First, a cold response contributes to pulpal diagnosis but should not be described as independently 'confirming' reversible pulpitis. Second, current AAPD permanent-tooth VPT guidance strongly recommends selective caries removal for deep caries in teeth diagnosed with normal pulp/reversible pulpitis.

Suggested correction: Use calibrated language: symptoms, examination, radiographs, and sensibility testing together support the pulpal diagnosis. For deep caries with NP/RP, describe selective caries removal to reduce unnecessary pulp

exposure; if exposure occurs, DPC, partial pulpotomy, or full pulpotomy may be considered according to clinical findings.

Case 4 - MIH with post-eruptive breakdown

Severity: MINOR

Test prompt (abridged): 7-year-old with newly erupted first permanent molar, yellow-brown demarcated opacity, hypersensitivity, cusp breakdown and exposed dentin; smaller opacities on other first molars.

> *AI: "Stainless-steel crowns are the most reliable long-term solution for severely broken MIH molars in children... a conventional composite filling alone would likely fail quickly."*

Evaluator finding: The diagnosis of MIH with post-eruptive breakdown is well supported by the case. The management framework also recognizes sensitivity, prevention, interim protection and full-coverage options. The weakness is over-certainty: AAPD describes preventive, short-term, intermediate and definitive pathways, and also discusses planned extraction/molar substitution when restoration is not feasible. The best option depends on severity, restorability, symptoms, dental development and occlusal/orthodontic considerations.

Suggested correction: Replace categorical 'most reliable'/'likely fail quickly' wording with conditional recommendations tied to lesion severity, remaining tooth structure, ability to obtain sound margins/isolation, child factors, and long-term restorative versus extraction planning.

Evaluation approach

For each output I would separate: (1) factual/clinical accuracy, (2) patient-safety risk, (3) unsupported assumptions, (4) uncertainty calibration, (5) guideline alignment, (6) pediatric realism, and (7) source quality. I would also retain PASS cases so the review measures model performance rather than simply collecting errors.

Severity rubric: **PASS** = no material clinical correction; **MINOR** = clinically useful answer with a precision, completeness, or evidence-calibration issue; **MAJOR** = recommendation could materially alter inappropriate management or requires substantive clinical correction; **CRITICAL** = plausible risk of serious harm requiring immediate escalation.

Reference framework

American Academy of Pediatric Dentistry (AAPD), Reference Manual of Pediatric Dentistry 2026-2027: Pulp Therapy for Primary and Immature Permanent Teeth; Guideline for Use of Vital Pulp Therapy in Permanent Teeth (2025); Molar-Incisor Hypomineralization best practice.

Prepared as an independent sample for review. No patient data were used; all cases are synthetic.
